

Exploring Alpha Generation through Fixed Income Arbitrages

Preliminary Empirical Results — All Three Strategies

March 3, 2026

BTP Italia Basis

Returns are built from opening positions whenever the basis between BTP Italia and the matched nominal BTP becomes sufficiently wide (positive or negative). Positions remain open until convergence or maturity. Daily trade-level returns are aggregated into a single equal-weighted strategy index, resampled to monthly frequency.

CDS–Bond Basis

Universe includes all EUR corporate bonds whose issuer belongs to the iTraxx Main at the trade date. We only trade *negative* basis (long bond / long protection), for which implementation is liquid and feasible. Trades remain open until the basis reverts or the bond approaches maturity. Daily returns across all active trades form the CDS–Bond Basis index.

iTraxx Index Skew

We use the four EUR indices (Main, Senior Financials, Subordinated Financials, Crossover). At each decision date, only the on-the-run series are considered, each with thresholds calibrated to its volatility. The most mispriced index (in absolute basis) is traded. Returns are aggregated into a single iTraxx Skew index.

We evaluate our three fixed-income arbitrage strategies under the established risk-factor models used in the literature:

- *Duarte, Longstaff & Yu (2007), Review of Financial Studies.*
Fixed-income arbitrage benchmark used to assess exposure to equity, credit and Treasury-based relative-value factors.
- *Fung & Hsieh (2004), Financial Analysts Journal.*
Trend-following and option-based factors widely used to benchmark hedge-fund strategies.
- *Brooks, Gould & Richardson (2020), Journal of Fixed Income.*
Active fixed-income premium decomposition: term, credit, EM, inflation-linked, and volatility premia.

US factors are mapped to their EUR counterparts. European equity factors use the Fama-French Europe datasets, converted from USD into EUR following the methodology of Glück, Hübel & Scholz (JPM, 2020). Trend-following factors (Fung-Hsieh) are global and directly applicable.

Two Approaches to Position Sizing

All three strategies involve multiple simultaneous open trades. The question is: *how much weight to assign to each trade when constructing the strategy index?*

Equal-Weight (EW)

Each open trade receives the same weight on any given day. The daily strategy return is the simple cross-sectional average of all active trade returns:

$$r_t^{EW} = \frac{1}{N_t} \sum_{k \in \mathcal{A}_t} r_{k,t}$$

where $\mathcal{A}_t$ is the set of active trades at t .

Benchmark approach, following Duarte et al. (2007).

Signal-Weight (SW)

Each trade is weighted by how rich the entry opportunity was relative to historical fair value. Following Rebonato and Ronzani (2021):

$$r_t^{SW} = \frac{\sum_{k \in \mathcal{A}_t} w_k r_{k,t}}{\sum_{k \in \mathcal{A}_t} w_k}$$

where $w_k = |b_k^{\text{entry}} - \theta_{t_k}|$, with θ_t the expanding-window historical mean of the aggregate basis.

Larger position when the basis is further from equilibrium.

The intuition: if the basis is unusually wide, the trade is more attractive *and* more likely to converge —

SW vs EW — Basic Metrics (Daily, Annualized)

Strategy	Return (% p.a.)	Vol (% p.a.)	Sharpe	MaxDD (%)	Skew	Kurt	$\Theta_{\rho=3}$ (% p.a.)	N
Panel A: EW								
BTP-Italia	1.74	2.49	0.70	-2.97	0.60	19.94	1.65	159
iTraxx <i>combined</i>	4.27	3.12	1.37	-2.04	0.62	5.41	4.12	242
CDS-Bond Basis	6.71	3.25	2.06	-4.05	4.45	81.74	6.55	203
Panel B: SW								
BTP-Italia	1.99	2.38	0.84	-2.97	0.73	23.33	1.90	159
iTraxx <i>combined</i>	4.85	3.39	1.43	-2.52	0.64	5.26	4.68	242
CDS-Bond Basis	7.55	3.55	2.13	-3.47	4.48	68.94	7.37	203

Note: Metrics computed from daily returns (annualization factor 252). MaxDD is computed on the wealth index. $\Theta_{\rho=3}$ is the Goetzmann et al. (2007) manipulation-proof measure.

SW vs EW — MPPM Comparison (Monthly)

Strategy	$\rho = 2$ (% p.a.)	$\rho = 3$ (% p.a.)	$\rho = 4$ (% p.a.)	Avg Ret (% p.a.)	Vol (% p.a.)	Sharpe	N
Panel A: EW							
BTP-Italia	1.62	1.61	1.59	1.65	1.77	0.93	163
iTraxx <i>combined</i>	3.98	3.95	3.93	4.03	2.10	1.92	243
CDS-Bond Basis	6.32	6.26	6.20	6.47	3.59	1.80	207
Panel B: SW							
BTP-Italia	1.86	1.85	1.83	1.89	1.71	1.11	163
iTraxx <i>combined</i>	4.51	4.49	4.46	4.58	2.39	1.91	243
CDS-Bond Basis	7.12	7.05	6.98	7.29	3.89	1.87	207

Note: MPPM is the Manipulation-Proof Performance Measure (Goetzmann et al. 2007). Computed from monthly returns compounded from daily. Risk-free is Euribor 1M (ACT/360), compounded to monthly.

SW vs EW — Volatility-Managed Performance (Monthly)

Strategy	Buy-and-Hold			Vol-Managed			Alpha	N
	Ret (% p.a.)	Vol (% p.a.)	Sharpe	Ret (% p.a.)	Vol (% p.a.)	Sharpe		
Panel A: EW								
BTP-Italia	1.57	1.74	0.90	0.41	1.74	0.23	-0.28	158
iTraxx <i>combined</i>	4.05	2.10	1.93	1.75	2.10	0.83	+0.15	241
CDS-Bond Basis	6.38	3.55	1.80	4.54	3.55	1.28	+2.79	202
Panel B: SW								
BTP-Italia	1.82	1.68	1.08	0.55	1.68	0.33	-0.14	158
iTraxx <i>combined</i>	4.62	2.40	1.93	1.85	2.40	0.77	-0.06	241
CDS-Bond Basis	7.22	3.86	1.87	5.44	3.86	1.41	+3.45	202

Note: Following Moreira and Muir (2017). The volatility-managed strategy scales positions inversely to realized variance: $f_{t+1}^{\sigma} = (c/\sigma_t^2) \times f_{t+1}$, where c matches buy-and-hold volatility. Alpha is from regressing VM returns on BH returns.

SW vs EW — Volatility-Managed Robustness (Monthly)

Strategy	Metric	No Leverage (≤ 1)	50% Leverage (≤ 1.5)	Table V [0.1, 2.0]
Panel A: EW				
BTP-Italia	Alpha (% p.a.)	+0.16	+0.17	+0.16
	Sharpe	0.84	0.79	0.79
iTraxx <i>combined</i>	Alpha (% p.a.)	+0.11	+0.11	+0.10
	Sharpe	1.27	1.11	1.09
CDS-Bond Basis	Alpha (% p.a.)	+0.80	+1.05	+1.15
	Sharpe	1.43	1.42	1.50
Panel B: SW				
BTP-Italia	Alpha (% p.a.)	+0.11	+0.14	+0.14
	Sharpe	0.90	0.89	0.91
iTraxx <i>combined</i>	Alpha (% p.a.)	+0.01	-0.08	-0.15
	Sharpe	1.10	0.94	0.92
CDS-Bond Basis	Alpha (% p.a.)	+1.00	+1.46	+1.64
	Sharpe	1.49	1.50	1.60

Note: Robustness tests following Table V in Moreira and Muir (2017). *No Leverage:* scaling $\in [0, 1]$. *50% Leverage:* scaling $\in [0.1, 2.0]$ as in the paper.

W is the rolling window length (months) used to estimate PCA factors; K is the number of retained principal components. Expl. Var. (%) is the average cumulative variance explained by the first K PCs (rolling, time-series average). Alpha is annualized (% p.a.). t-statistics in parentheses (Newey-West HAC). Pred = $PC_t \rightarrow R_{t+1}$, Cont = $PC_t \rightarrow R_t$. *** p<0.01, ** p<0.05, * p<0.10.

To strengthen the risk-adjustment side beyond the standard benchmarks, I conducted an extensive review of the recent fixed-income and arbitrage literature and **reconstructed the full historical time-series dataset** for a comprehensive set of candidate risk controls (80+ factors). Each series was rebuilt consistently with the original paper definitions (transformations, shocks/innovations, lags, and frequency alignment).

Factor universe (organized in 6 families)

- *Credit risk* (e.g., CDS indices, excess bond premium, sovereign spreads)
- *Liquidity & funding stress* (e.g., OIS spreads, repo indicators, noise/illiquidity measures)
- *Equity / intermediary proxies* (e.g., BAB, value, momentum)
- *Volatility* (e.g., VIX/V2X, MOVE, option-implied measures, trend-following)
- *Macro uncertainty & policy* (e.g., uncertainty indices, EPU, financial conditions)
- *Rates & term structure* (e.g., term, slope, swap spreads)

Next: full factor list (as a “menu”) and then a parsimonious spanning set will be identified for each strategy.

Risk Factors Universe (Literature-Based, Reconstructed Series) I

Factor ID	Description	Reference
Panel A: Credit Risk Factors		
BTP_BUND	Yield differential between the Italian 10-year BTP and the German Bund.	Fausch and Sigonius (2018)
CDX_IG	First difference of the CDS spread on the CDX Investment Grade index.	Klaus and Rzepkowski (2009)
CREDIT_EU	Same construction as CREDIT_US, computed using Bloomberg euro-area corporate bond yield indices for BBB and AAA ratings.	Fama and French (1989)
CREDIT_US	Bond credit risk factor. Yield spread between Moody's BAA and AAA corporate bond indices.	Fama and French (1989)
DEF_EU	Same construction as DEF_US, computed using long-term European corporate bond total returns relative to long-term German Bund total returns.	Fama and French (1993)

Risk Factors Universe (Literature-Based, Reconstructed Series) II

DEF_US	Bond default risk factor. Total return spread between a long-term U.S. corporate bond portfolio and a long-term U.S. government bond portfolio.	Fama and French (1993)
EBP	Excess Bond Premium. Residual component of aggregate corporate bond spreads after netting out expected default risk and bond characteristics via cross-sectional spread regressions; proxies time-varying credit risk compensation tied to intermediary constraints. Used with a one-month lag.	Gilchrist and Zakrajšek (2012)
ITRX_MAIN	First difference of the CDS spread on the iTraxx Europe Main index.	Klaus and Rzepkowski (2009)
MAIN_5/3_FLATTENED	First difference of the natural logarithm of the ratio between the 5-year and 3-year iTraxx Europe Main CDS spreads.	Market indicator
PB_EU_CDS_1Y	Average 1-year CDS spread of European prime brokers.	Klaus and Rzepkowski (2009)
PB_EU_CDS_5Y	Average 5-year CDS spread of European prime brokers.	Klaus and Rzepkowski (2009)
PB_US_CDS_1Y	Average 1-year CDS spread of U.S. prime brokers.	Klaus and Rzepkowski (2009)

Risk Factors Universe (Literature-Based, Reconstructed Series) III

PB_US_CDS_5Y	Average 5-year CDS spread of U.S. prime brokers.	Klaus and Rzepkowski (2009)
SNR-MAIN	First difference of the 5-year CDS spread difference between the iTraxx Senior Financials index and the iTraxx Europe Main index.	Market indicator
XOVER/MAIN	First difference of the natural logarithm of the ratio between the 5-year iTraxx Crossover and 5-year iTraxx Europe Main CDS spreads.	Market indicator

Panel B: Liquidity Factors

Δ FAILS_PCT_TSY	First difference of the ratio of Monthly total notional amount of U.S. Treasury securities fails-to-deliver reported by primary dealers, excluding TIPS, to U.S. Total Debt Outstanding, expressing repo fails as a share of total marketable U.S. Treasury debt.	Fleckenstein et al. (2014)
EURIBOR_OIS	Euribor–OIS spread. Difference between 3-month Euribor and the 3-month overnight index swap rate based on EONIA or €STR.	Nyborg and Östberg (2014)
GC-REPO_T-BILL	Spread between the 3-month U.S. Treasury general-collateral repo rate and the 3-month U.S. Treasury bill yield.	Bai and Collin-Dufresne (2019)

Risk Factors Universe (Literature-Based, Reconstructed Series) IV

HKM_IC	Intermediary capital factor. AR(1) innovation in the market-based capital ratio of primary dealers, scaled by the lagged capital ratio.	He et al. (2017)
HPW_NOISE	Treasury noise measure of market-wide illiquidity. Root mean squared deviation between observed U.S. Treasury yields and model-implied yields from a fitted smooth zero-coupon yield curve, aggregated across bonds with maturities between 1 and 10 years.	Hu et al. (2013)
ILLIQ	Change in the Amihud illiquidity measure. First difference of the ratio of absolute daily return to daily dollar volume, capturing shocks to market illiquidity.	Amihud and Mendelson (2015)
LIBOR_OIS	Libor–OIS spread. Difference between 3-month LIBOR and the 3-month overnight index swap rate.	Nyborg and Östberg (2014)
LIBOR_REPO_SHOCK	Defined as the AR(2) residual of the spread, where the spread is the monthly average of daily 3-month U.S. interbank LIBOR minus the 3-month U.S. Treasury general-collateral repo rate.	Asness et al. (2013)
LIQ_V	Value-weighted return on a 10–1 portfolio formed by sorting stocks on historical liquidity betas.	Pástor and Stambaugh (2003)
LIQNT	Pastor–Stambaugh non-traded liquidity factor. Innovation in aggregate market liquidity constructed from a cross-sectional average of stock-level order-flow-induced return-reversal measures, with predictable components removed.	Pástor and Stambaugh (2003)

Risk Factors Universe (Literature-Based, Reconstructed Series) V

SILLIQ	Stock illiquidity shock. Innovation in the monthly stock-market illiquidity series, defined as the AR(3) residual of the aggregate Amihud illiquidity measure.	Acharya et al. (2013)
TED_SHOCK_EU	Same construction as TED_SHOCK_US, computed using the monthly average of daily 3-month Euribor minus the 3-month German government bill rate.	Asness et al. (2013)
TED_SHOCK_US	Defined as the AR(2) residual of the TED spread, where the TED spread is the monthly average of daily 3-month U.S. interbank LIBOR minus the 3-month U.S. government bill rate.	Asness et al. (2013)

Panel C: Equity Factors

BAB_EU	Betting Against Beta (Europe). Same construction as BAB_US, implemented on the European equity universe.	Frazzini and Pedersen (2014)
BAB_US	Betting Against Beta (US). Long low-beta stocks and short high-beta stocks; each leg is rescaled to unit beta, forming a near market-neutral zero-cost factor.	Frazzini and Pedersen (2014)
CMA_EU	Investment factor (Conservative Minus Aggressive). Return spread between European conservative and aggressive investment portfolios from independent size-investment sorts.	Fama and French (2017)

Risk Factors Universe (Literature-Based, Reconstructed Series) VI

GMOM_EU	Global momentum factor. Return spread between recent winner and loser equity portfolios based on past 12-month returns excluding the most recent month, expressed in euros.	Asness et al. (2013)
GVAL_EU	Global value factor. Return spread between high and low book-to-market equity portfolios formed within major developed equity regions, expressed in euros.	Asness et al. (2013)
HML_EU	Value factor (High Minus Low). Return spread between European high and low book-to-market portfolios from independent size-B/M sorts, approximately size-neutral.	Fama and French (2017)
MKT_EU	Market excess return on the European value-weighted equity market portfolio over the 1-month German government bill. Returns are expressed in euros.	Fama and French (2017)
RMW_EU	Profitability factor (Robust Minus Weak). Return spread between European robust and weak operating profitability portfolios from independent size-profitability sorts.	Fama and French (2017)
SMB_EU	Size factor (Small Minus Big). Return spread between diversified European small- and large-cap portfolios from independent size sorts (five-factor construction).	Fama and French (2017)
UMD_EU	Momentum factor (Up Minus Down). Monthly return on a European zero-investment winners-minus-losers momentum portfolio.	Carhart (1997)

Risk Factors Universe (Literature-Based, Reconstructed Series) VII

Panel D: Volatility Factors

$\Delta V2X$	Change in V2X. Monthly first difference of the V2X index, the European counterpart of VIX measuring 30-day implied volatility on Euro STOXX 50 options.	Chung et al. (2019)
ΔVIX	Change in VIX. Monthly first difference of the VIX index, a model-free measure of 30-day implied volatility on S&P 500 options.	Chung et al. (2019)
ATM_IV_CDX	3-month at-the-money implied volatility on options written on the CDX Investment Grade index.	Novales and Chamizo (2019)
ATM_IV_ITRX	3-month at-the-money implied volatility on options written on the iTraxx Europe Main index.	Novales and Chamizo (2019)
EP_SVIX_1M	Equity premium proxy from the SVIX methodology. Option-implied risk-neutral variance of the market simple return over the next month, computed by integrating out-of-the-money index option prices across strikes.	Martin (2017)
EP_SVIX_3M	Same construction as EP_SVIX_1M, using options with a 3-month horizon.	Martin (2017)
IV_BUND	3-month at-the-money implied volatility on the 10-year German Bund futures options, based on 100% moneyness.	Cremers et al. (2021)

Risk Factors Universe (Literature-Based, Reconstructed Series) VIII

IV_TSY	3-month at-the-money implied volatility on the 10-year U.S. Treasury futures options, based on 100% moneyness.	Cremers et al. (2021)
MOVE	Option-implied U.S. rates volatility. Yield-curve weighted average of at-the-money implied normal yield volatilities from OTC options on 2-, 5-, 10-, and 30-year constant-maturity interest rate swaps; used lagged by one month.	Bansal and Stivers (2022)
MOVE2	Squared MOVE; used lagged by one month to capture nonlinear exposure to option-implied U.S. interest rate volatility.	Bansal and Stivers (2022)
PTFSBD	Return on the bond trend-following factor, constructed from lookback straddles on government bond futures.	Fung and Hsieh (2001)
PTFSCOM	Return on the commodity trend-following factor, constructed from lookback straddles on commodity futures.	Fung and Hsieh (2001)
PTFSFX	Return on the currency trend-following factor, constructed from lookback straddles on major currency futures.	Fung and Hsieh (2001)
PTFSIR	Return on the short-term interest rate trend-following factor, constructed from lookback straddles on 3-month interest rate futures.	Fung and Hsieh (2001)

Risk Factors Universe (Literature-Based, Reconstructed Series) IX

PTFSSTK	Return on the equity index trend-following factor, constructed from lookback straddles on stock index futures.	Fung and Hsieh (2001)
---------	--	-----------------------

Panel E: Macro Factors

$\Delta U F$	Change in financial uncertainty. First difference of the financial uncertainty index, constructed as $\Delta U M$ but using a panel of financial market variables.	Ludvigson et al. (2021)
$\Delta U M$	Change in macroeconomic uncertainty. First difference of the macro uncertainty index, a model-based measure of expected volatility in the unforecastable component of a large panel of macroeconomic variables.	Ludvigson et al. (2021)
$\Delta U R$	Change in real uncertainty. First difference of the real-activity uncertainty subindex, constructed from real activity variables.	Ludvigson et al. (2021)
5Y5YREAL_YIELD	First difference of the spread between the 5y5y interest rate swap rate and the 5y5y inflation swap rate.	Market indicator
BFCI_EU	Bloomberg Euro Area Financial Conditions Index. Composite Z-score of euro-area money, bond, and equity indicators, standardized to the 1999 to July 1, 2008 pre-crisis period and expressed in standard deviations from pre-crisis conditions.	Osina (2019)
EPU_EU	Economic Policy Uncertainty index for Europe. Same construction as EPU_US, implemented on European newspapers and aggregated across European countries.	Baker et al. (2016)

Risk Factors Universe (Literature-Based, Reconstructed Series) X

EPU_US	Economic Policy Uncertainty index for the United States. Newspaper-based index constructed from the normalized frequency of articles that jointly reference the economy, uncertainty, and policy-related terms.	Baker et al. (2016)
--------	---	---------------------

Panel F: Interest Rate Factors

Δ SLOPE_EU	Same construction as Δ SLOPE_US, computed using the 10-year German government bond yield minus the 3-month German government bill yield.	Ferson and Harvey (1991)
Δ SLOPE_US	First difference of the U.S. yield-curve slope, defined as the 10-year Treasury yield minus the 3-month Treasury bill yield.	Ferson and Harvey (1991)
EURUSD_3M_IV	First difference of the 3-month at-the-money implied volatility on the EUR/USD exchange rate.	Market indicator
SS2Y	Difference between the 2-year EUR fixed swap par rate and the 2-year German Schatz yield.	Collin-Dufresne et al. (2001)
SS5Y	Difference between the 5-year EUR fixed swap par rate and the 5-year German Bobl yield.	Collin-Dufresne et al. (2001)

Risk Factors Universe (Literature-Based, Reconstructed Series) XI

SS10Y	Difference between the 10-year EUR fixed swap par rate and the 10-year German Bund yield.	Collin-Dufresne et al. (2001)
TERM_EU	Same construction as TERM_US, computed using long-term German Bund total returns in excess of the 1-month German government bill return.	Fama and French (1993)
TERM_US	Bond term structure factor. Excess total return on long-term U.S. government bonds over the 1-month U.S. Treasury bill return.	Fama and French (1993)
YSP_EU	Yield-curve slope factor. Difference between the 5-year and 1-year German government bond yields.	Koijen et al. (2017)
YSP_US	Yield-curve slope factor. Difference between the 5-year and 1-year U.S. Treasury yields.	Koijen et al. (2017)

From PCA to a Parsimonious Factor Benchmark

PCA spanning regressions show alpha is **large and significant** across all three strategies, but explain **little variation** in returns (adj. R^2 typically below 10%) — the PC loadings mix all 80+ factors indiscriminately, offering no economic interpretation.

What we want instead: a *small, named* set of risk factors that best spans each strategy's returns and lets us assess whether alpha reflects a genuine anomaly or compensation for an overlooked risk.

Challenge: with $p \approx 80$ candidate factors and T between 150 and 240 monthly observations depending on the strategy, standard OLS is technically feasible but unreliable:

- Strong multicollinearity across factors (credit spreads, liquidity proxies, rate factors all move together) produces unstable coefficient estimates and inflated standard errors
- With no selection discipline, in-sample fit is deceptively high and alpha inference is unreliable

We rely on **machine learning** — specifically the Adaptive Elastic Net — to perform principled, data-driven factor selection.

Why not plain LASSO? LASSO (Tibshirani, 1996) penalizes all coefficients equally and tends to pick one factor arbitrarily when several are correlated — known to be selection-inconsistent in this setting.

Why not Ridge? Ridge shrinks all coefficients toward zero but never sets any exactly to zero — no variable selection, no parsimony, no interpretable benchmark.

Adaptive Elastic Net (Zou and Zhang, 2009) combines both penalties with factor-specific weights:

- ℓ_1 penalty $\Rightarrow$ exact zeros (automatic factor selection)
- ℓ_2 penalty $\Rightarrow$ handles correlated groups of factors gracefully
- adaptive weights $\Rightarrow$ *oracle property*: asymptotically selects the correct model and produces unbiased estimates on the selected set

The result is a **sparse, interpretable factor benchmark** — typically 4–8 named factors per strategy — that can be used for credible alpha inference.

Step 1 — Elastic Net first pass. Solve the convex problem:

$$\hat{\beta}^{EN} = \arg \min_{\beta} \left\{ \frac{1}{T} \sum_{t=1}^T (r_t - \alpha - \beta' f_t)^2 + \lambda_2 \|\beta\|_2^2 + \lambda_1 \|\beta\|_1 \right\}.$$

Step 2 — Construct adaptive weights. For each factor j : $w_j = |\hat{\beta}_j^{EN}|^{-\gamma}$ ($\gamma = 1$). Factors weakly selected in Step 1 receive *higher* penalty.

Step 3 — Adaptive Elastic Net. Re-solve with factor-specific penalties:

$$\hat{\beta}^{AEN} = \arg \min_{\beta} \left\{ \frac{1}{T} \sum_{t=1}^T (r_t - \alpha - \beta' f_t)^2 + \lambda_2 \|\beta\|_2^2 + \lambda_1 \sum_{j=1}^p w_j |\beta_j| \right\}.$$

Solution method. Both problems are *strictly convex* (unique global minimum). The solution is obtained via **coordinate descent**: each β_j is updated cyclically in closed form (soft-thresholding with ridge correction) until convergence — no matrix inversion, no gradient approximation (Friedman et al., 2010).

Tuning. (λ_1, λ_2) selected by minimizing the **Hannan–Quinn criterion** (HQC), which penalizes model complexity as $2 \log(\log T) \cdot k$, intermediate between AIC and BIC — appropriate for our $T \approx 158$.

Stability Selection: Guarding Against Sample-Specific Factors

A single AEN run on the full sample may select factors that are artefacts of the specific time period.

We apply **stability selection** (Meinshausen and Bühlmann, 2010), adapted for time-series dependence:

- 1 Draw $B = 1000$ bootstrap resamples using a **stationary block bootstrap** (Politis and Romano, 1994) with expected block length $L = 9$ months, preserving autocorrelation structure.
- 2 For each resample, run the full AEN procedure and record which factors are selected.
- 3 Compute each factor's **selection frequency** $\hat{\pi}_j \in [0, 1]$ across the B resamples.
- 4 Retain only factors with $\hat{\pi}_j \geq \pi^* = 0.60$.

Theoretical guarantee (Meinshausen and Bühlmann, 2010): under mild conditions, the expected number of falsely selected factors is bounded by $q^2/[p(2\pi^* - 1)]$, where q is the maximum model size per draw.

The final stable factor set $\hat{S}_i$ is used for post-selection OLS inference.

Once the stable factor set $\hat{S}_i$ is identified, we estimate an unrestricted OLS on those factors:

$$r_{i,t} = \alpha_i + \beta_i' f_{\hat{S}_i,t} + \varepsilon_{i,t}, \quad t = 1, \dots, T.$$

Penalized AEN coefficients are intentionally shrunk and not directly interpretable — OLS on the selected set recovers unbiased estimates. Standard errors are Newey–West HAC with 6 lags.

All three strategies deliver **significant, risk-adjusted alpha** that survives both standard benchmarks and machine-learning factor selection (80+ factors, AEN).

The natural follow-up question: if alpha is real, why doesn't capital eliminate it?

Duffie (2010) — Slow-Moving Capital:

- Intermediary capital moves slowly across markets due to balance sheet constraints, margin requirements, and search frictions
- When arbitrageurs face funding pressure in one market, they *reduce positions across multiple markets simultaneously*
- **Testable prediction:** mispricing magnitudes should co-move, especially during financial stress

Our test: construct mispricing magnitudes $m_{i,t}$ for each strategy and examine whether Δm co-moves across markets, whether the common factor reflects funding stress, and whether interdependence intensifies in HIGH-stress regimes.

Mispricing magnitude $m_{i,t} \geq 0$, increasing with the size of the opportunity:

CDS–Bond Basis

$$m_t = -\text{basis}_t$$

(only when basis < 0)

Negative basis = arb opportunity.

NaN when basis ≥ 0 .

BTP Italia

$$m_t = |\text{basis}_t|$$

Mispricing exists in both directions.

m increases as basis deviates from zero.

iTraxx Combined

$$m_t = |\text{basis}_t|$$

Same construction as BTP Italia.

For all three: $\Delta m_t > 0 \Rightarrow$ **widening** (mispricing grows, more capital needed).

Regime classification: iTraxx Main level with manual thresholds (no look-ahead):

- **LOW:** Main ≤ 60 bps (55 months)
- **MEDIUM:** $60 < \text{Main} \leq 120$ bps (83 months)
- **HIGH:** Main > 120 bps (9 months)

Robustness: iTraxx Crossover, VIX, V2X; percentile-based regimes. Trivariate overlap: $T = 144$ months (Jun 2012 – Mar 2025).
